

PLANGYM

Resume

PlanGym is a web application developed as part of the Final Project for the Higher Level Vocational Training Certificate in Web Application Development at I.E.S. Fernando Wirtz Suárez. The motivation for this project was the lack of simple and free tools for planning gym workouts. The main objective was to create a functional website that would allow users to register, create personalized training routines, track completed workouts using a calendar, and consult a catalog of exercises. The backend was developed with Python and Flask, following a layered architecture that separates routes, services, repositories, and models. User data is stored in an SQLite database managed using SQLAlchemy. The application also integrates the external API wger.de to obtain real-time exercise data, implementing a local alternative in case the API is unavailable. The frontend was built with HTML, CSS, and JavaScript, using asynchronous requests to communicate with the backend. The project fulfills its main objectives: users can log in, manage their routines by assigning exercises to specific days of the week, and monitor their training activity over time. Automated tests were written to test the main business logic.
